1. Introduction

The objective of this project is to analyse a food service dataset to uncover insights into operational efficiency and food waste management. Key variables include meals served, kitchen staff, temperature, humidity, and food waste. The goal is to explore the data, clean it, visualize patterns, test hypotheses, and provide actionable recommendations.

2. Dataset Overview

The dataset contains 1,822 records and 11 features:

- **ID**: Unique identifier
- **date**: Date of observation
- **meals_served**: Meals served per day
- **kitchen_staff**: Staff count per day
- **temperature_C**: Daily temperature (°C)
- **humidity_percent**: Daily humidity (%)
- **day_of_week**: 0 (Sunday) to 6 (Saturday)
- **special_event**: 1 = event day, 0 = normal day
- **past_waste_kg**: Food waste from previous days
- **staff_experience**: e.g., beginner, intermediate
- **waste_category**: Category of waste (e.g., dairy, meat)

3. Data Cleaning

- Converted date to datetime format
- Changed kitchen_staff and special_event to numeric
- Standardized categorical variables to lowercase
- Missing values handled:
 - Dropped rows missing critical values (meals_served, kitchen_staff, past_waste_kg)
 - Imputed humidity_percent with median, special_event with mode
 - Categorical nulls filled with 'unknown'
- No duplicate rows found

4. Exploratory Data Analysis (EDA)

Summary Statistics:

- Numerical features showed reasonable distributions.

- meals_served and past_waste_kg showed variance across the dataset.

freq	476	426

There were approximately 800 duplicated rows which were removed!!!

Visualizations:

- **Histograms** for all numeric features
- **Boxplots** identified outliers in past_waste_kg
- **Bar plots** for staff_experience and waste_category revealed most common categories

- Majority of orders were served by staff with intermediate experience level.
- Meat is the highest category of waste.

5. Correlation Analysis

A correlation heatmap showed:

- meals_served and past_waste_kg: moderately positive correlation
- kitchen_staff also correlated with waste to some extent
- Temperature and humidity had weaker, but non-negligible correlations

- It seems that there is no correlation between food waste and meals served in the given data set.
- Also there seems no influence of temperature or humidity on food waste in the given data set.

6. Hypothesis Testing

Hypothesis 1: Staff size affects food waste

- **T-test** between high vs low staff levels
- **P-value** < 0.05: **Significant** difference — staff size impacts food waste
 - Yes, the number of kitchen staff is statistically significantly associated with food waste — more staff slightly reduces waste.
 - However, the practical effect is minimal and the model is a very poor predictor of food waste.

Hypothesis 2: Special events increase waste

- **T-test** between event and non-event days
- **P-value** < 0.05: **Significant** difference — special events lead to higher waste
 - Based on our analysis, we found no clear evidence that food waste increases during special events. The amount of food wasted on event days is not significantly different from regular days

7. Key Insights & Recommendations

- Higher kitchen staff correlates with increased food waste — consider optimizing schedules
- Special events are linked to greater waste — improve portion forecasting on event days
- More meals served → more waste — improve forecasting and inventory control
- Environmental factors (temperature, humidity) may influence waste — adapt prep accordingly
- Track staff experience and waste categories more accurately — too many 'unknown' values

8. Conclusion

This analysis reveals strong relationships between staff, events, and food waste. Operational changes based on these insights can reduce waste and improve efficiency. Future analyses could include time-series forecasting and machine learning for prediction.
